## Introduction

Pottery is one of the most iconic and tangible elements of regional art. Its history is quite ancient in the Indian subcontinent. Though the products here are mostly slip-cast (one of the techniques of large scale production), their uniqueness lies in their design quotient and color palette. A lot of intricate patterns are hand-painted in bright blues, greens, oranges, yellows and reds.

## Place

Khurja is a small city in the Bulandshahr District of Uttar Pradesh. It is often called as 'The Ceramics City' with its skyline dotted with chimneys. The industry manufactures products like tableware (crockery), sanitary-ware, insulators, hospital ware, chemical porcelain, electro ceramics, kiln furniture, decorative wares, toys and figurines. These are exported worldwide and some are distributed across India.

CGCRI (Central Glass and Ceramic Research Institute) has been continuously providing testing and technical facilities to the units for their upliftment. It works independently and is serving adequately for the growth of the industry.

## People

This craft is mostly practiced by the Muslim community, specially the intricate hand-painting on the planters with cobalt oxide that gets fired into the legendary blue. Traditionally, in most of the potter communities in India, women are not allowed to work on the wheel. In Khurja too, the men do the casting while the women only take care of the finishing or 'cleaning up'. Ceramic production requires good teamwork and synchronization. The people here are terrific at that. Over 500 factories provide employment to more than twenty five thousand people in the city and around.

## Process

There are many forming techniques to make ceramics, one of them is casting. This is the most efficient and cost effective way for large-scale production. In one factory, on an average, fifty thousand cups are churned out everyday. The process includes the following steps:

Clay Preparation

Casting

Glaze Application

Firing

Sticker Application

Quality Check & Packaging

## Clay Preparation

The basic raw material for making any ceramic product is clay and that could be of several types - china clay, fire clay, ball clay etc. Clay in powder form is sourced from Rajasthan and Gujarat. It is mixed in varying proportions with other raw materials to make clay that is ready-to-use. This is done in-house and the mix is churned in large machines. After this it goes to the filter press that makes cakes (discs) of clay and removes impurities. This is further rolled out through an electric pug-mill and becomes void of any kind of air bubbles, ready for casting.

Commonly used clay types while making Khurja include:

- **Stoneware** : 50% ball and china clay, 50% stone (25% quartz, 25% feldspar)
- **Bone China**: 50% ball and china clay, 50% bone ash (calcium phosphate)
- **Porcelain** : Quartz, feldspar and china clay

The choice of clay depends on temperature of firing, desired quality and finish of the product.

## Casting

Once the clay is ready to use, type of product to be made is decided. For eg. Cup, plate, vase, planter etc. Then the 'master copy' (sample) of the product is made (by hand or on the wheel). This is used as reference to make the mould and then finally 'multiple copies' are made.

## Mould Making

Moulds are made with POP (Plaster of Paris) mixed in water. This liquid is poured in the gap between the 'master copy' and a plain POP cylindrical mould. A coat of oil and soap solution is brushed on each surface to prevent sticking. The POP that gets poured takes the shape of the master copy from the inside and remains plain outside. This mould is usually made in parts-that-make-up-a-whole to eventually make the clay-cast easy to remove. Many moulds are prepared for one type of product to make production faster.

<http://www.dsource.in/resource/ceramics-khurja/process/casting/slip-casting>

## Slip Casting

In this step, the slip (clay mixed in water) is poured into the plaster moulds. The water in the slip is drawn out by the POP (as it absorbs water), leaving an inside layer of solid clay that acquires the shape of the mould. When this is thick enough, the excess slip is poured out from the mould. Nowadays, a lot of people use clay instead of slip to make simpler products like cups and mugs. This makes casting faster and less messy. The clay is 'thrown' in along the walls of the mould using a hand tool on a rotating wheel-head.

When the clay inside the mould is dry enough, it is removed by opening up parts of the mould that are held together with rubber bands. Handles of cups, animal shaped mugs, incense stick holders, flower shaped plates etc. are all cast in similar way. Mostly women take up the task of finishing ('cleaning up') the rough edges of these objects with a sponge soaked in water. These are then left to dry in the sun.

## Glaze Application

Once sun-dried, the karigars start painting on the product with 'stains' (ceramic colors, as they call it). These are usually applied as an under-glaze, and get fired to almost the same color as they are in powder form. A variety of patterns are painted, stenciled, sprayed on the ware. Once the stains are a bit dry, these pieces are dipped in clear glaze that would give them a glossy (glass) layer after firing. Sometimes, these are glazed plain white, without any stains, to be 'decorated' with stickers later.

## Ceramics of Khurja

The Craft of Clay

by

Sakshi Gambhir

IDC, IIT Bombay

**Source:**

<http://www.dsource.in/resource/ceramics-khurja/process/firing>

## Firing

In Khurja, all the stoneware pieces (that have stain painting and clear glaze on them) go through a single round of firing. This is greatly cost effective. Bone china, on the other hand usually undergoes three rounds - bisque firing, glaze firing and sticker firing - all separately. So, it is usually a bit more expensive. Mostly the firing is carried out with diesel fuel.

Firing in the kiln takes the ware through three zones:

- Pre - Heating zone (about 600 degrees),
- Heating zone (about 1200 degrees) and
- Cooling zone (about 480 degrees).

On an average, one car (container trolley) of the furnace containing 1680 pieces of cups would take 15 hours to run the length of the furnace (about 110 feet). So, the ware that one feeds from the pre-heating end can be taken out from the cooling end in fifteen hours, ready to be used or worked upon further.

## Sticker application

Stickers are usually applied as 'decoration' on bone china ware. This involves soaking the sticker in water for about fifteen seconds and then placing its peel on to the cup. This 'sticking' is obviously temporary, unless fired. Sticker firing is done only to fuse it with the clay body and is carried out at a much lower temperature. Any design created digitally on the computer can be printed as a sticker. Most of the big tea companies get these cups and saucers custom-made in Khurja for their free-gift-with-tea-box offers!

## Quality Check & Packaging

Quality check largely includes discarding the pieces that have a fault or are not well finished. The ones that pass the quality check are carefully packed in thermocol and cardboard boxes to be transported to its buyer.
